NEXONAI CONSULTING SRL

unpruuf Business

Your communication system. And nobody else's.

No provider. No account. No ID. Your infrastructure, your keys, your nodes.

THE PROBLEM

Every messenger has an owner

The provider's servers

All messages run over someone else's infrastructure.

Account and phone number

Every user is identifiable from day one.

Metadata

Who, with whom, when and how often: visible to the provider.

Even with end-to-end encryption, the provider remains the third party that can be forced to hand over data.

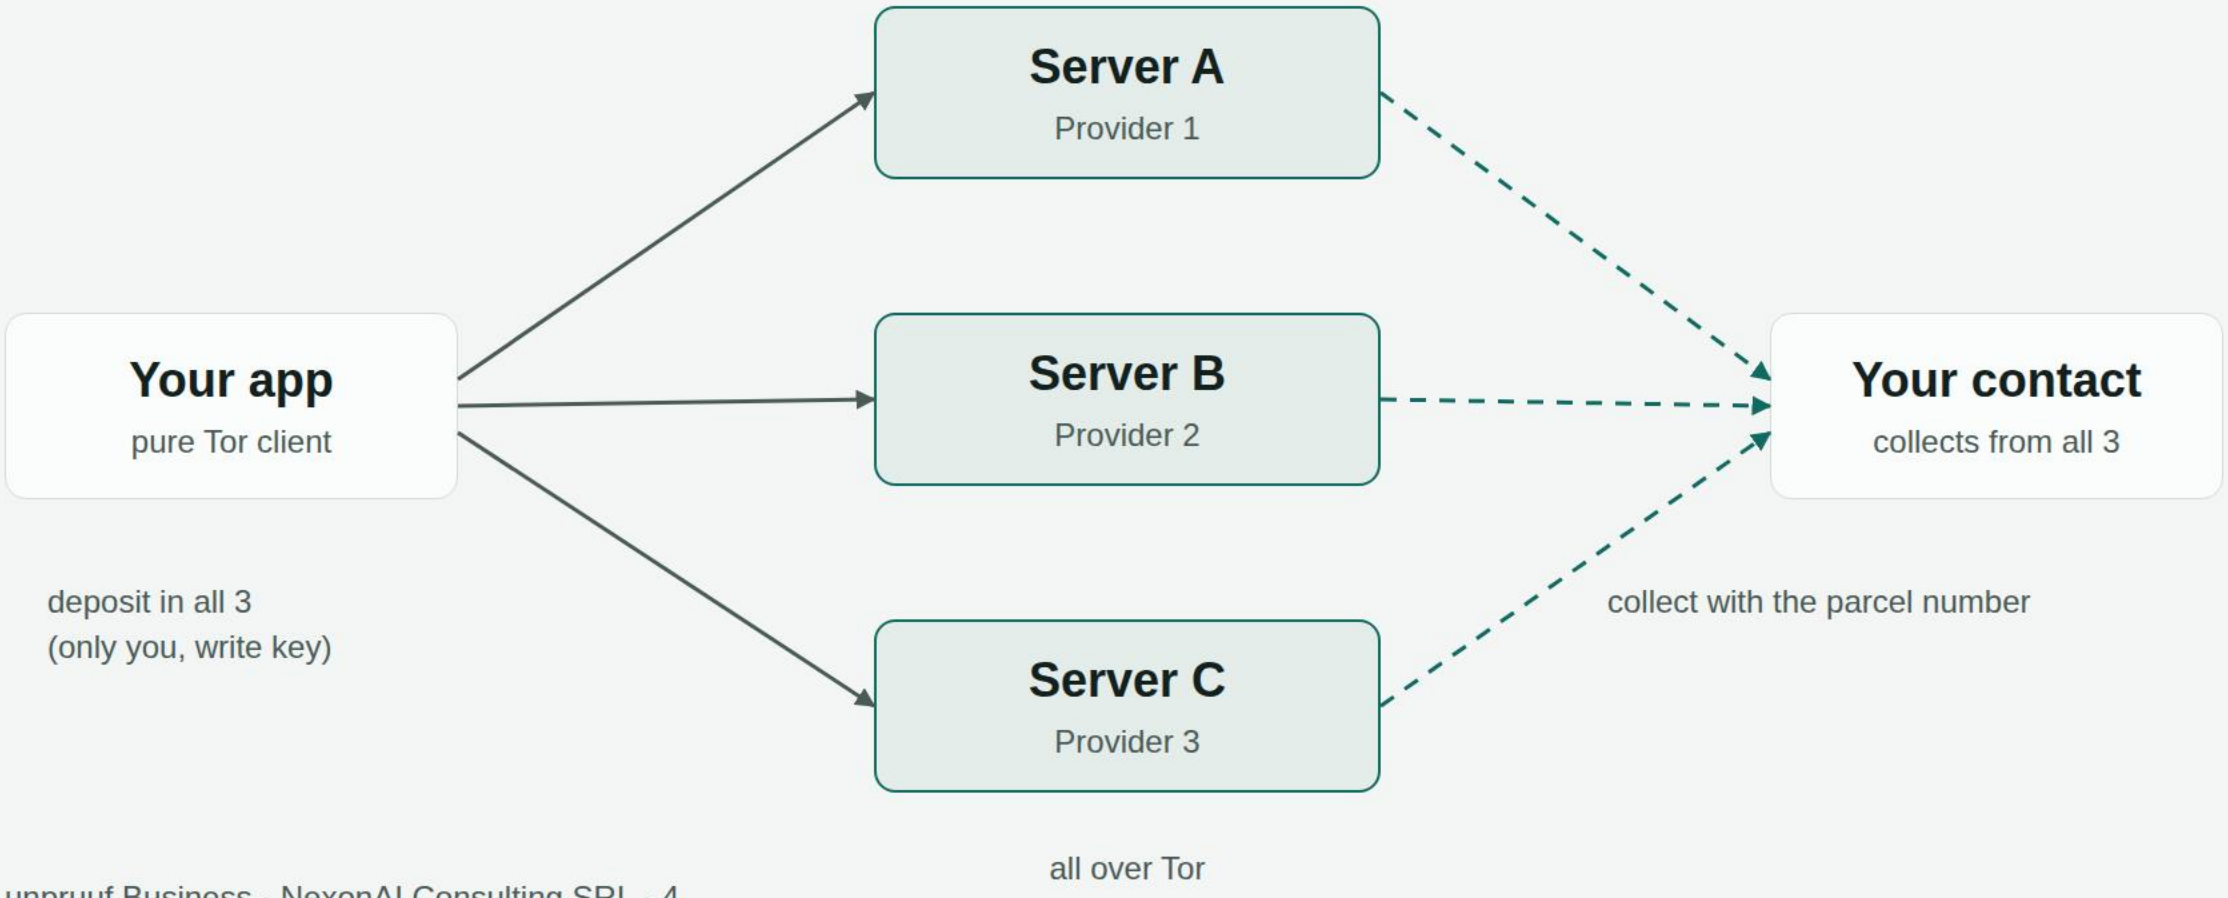

THE TOOL

Your server.
250 addresses of your own.

- Registered nowhere.
- Only you can write to it.
- Only those who are invited know an address.

HOW IT WORKS

Every message lies on three servers

IDENTIFICATION

Two things. Nothing more.

The parcel number

Finds the parcel without naming anyone. Changes every hour; both sides calculate it themselves.

The key

Makes the content readable. Only the two conversation partners have it, and it changes with every message.

The app does not know who it is talking to. It only needs a number to find the parcel and a key to decrypt it.

WHAT DOES NOT EXIST

Nothing that identifies

~~User ID~~

~~Account~~

~~Provider~~

~~Phone number~~

~~Onion address on the phone~~

~~Anything shared between contacts~~

Every pairing gets new keys and nodes of its own. Two contacts who compare their QR codes find nothing in common.

HOW IT WORKS

Never give out your phone number again

You share a code. Delete the contact, and there is no way to you any more.

A code, not a number

Every contact gets their own code. No phone number, no email, no WhatsApp, no shared address book.

One code per person

From the codes alone, two contacts cannot be linked. Whoever holds one learns nothing about your other contacts.

Delete, and it is over

Your phone stops collecting from that person. There is no way to you any more, unless you hand over a new code.

What someone has already received stays with them. This closes the unpruuf path, not your other channels.

SCALE

250 nodes per server, 3 per contact

250

Nodes per server, in one process. The number is set by the licence and cannot be changed.

3

nodes of their own for every new contact, spread over 3 servers

250

contacts with completely separate addresses on 3 servers

One file per server: the app imports all addresses as a list and gives each contact its own. A seized node affects only a few contacts, not all of them.

RESILIENCE

Three servers, three providers, no outage

3 × 250

750 addresses on 3 separate servers

2

servers may fail, every message still arrives

3

providers, preferably in different countries

Every message goes into all three mailboxes of the contact, and the contact checks all three. Hosting for three small servers: from about 10 euros a month (rule of thumb).

SERVER LISTS

You decide which servers carry which contacts

Import a list

The server saves its addresses as a file. The app imports it as a list, for example per customer or site.

Choose a list

When adding a contact you choose a list. The app picks 3 nodes from it automatically.

Several servers per list

If a list holds several servers, the three nodes of a contact have different operators.

This way it is always traceable which servers carry which contact.

THE NODE

What the node sees, and what it does not

Sees

Encrypted blocks of fixed size under numbers that change every hour. Deletes them itself after 1 to 24 hours.

Does not see

The content. The sender. The recipient. The IP address. Who belongs to whom.

A seized or stolen server contains nothing readable and only runs again after a restart once your app releases it.

THE SERVER IN PRACTICE

Installation without a command line

Everywhere

Windows, Linux, Docker, as .exe, or an Android tablet as a node.

Setup

install.bat and start.bat. The setup page accepts the licence code and shows the QR code.

List for the app

One click saves all addresses of the server as a file for your own app.

Overview

A page of its own shows nodes, packets and load. Quantities only, never content.

Profiles

Standard 6 hours, high security 1 hour, offline-tolerant 24 hours.

Temp Node

For one conversation only, in memory only. Closed = gone.

BUILT-IN SECURITY

Six layers, no promise

Tor mandatory

The node never sees an IP address.

Proof-of-Work

Flooding the node costs the attacker computing power.

Only the owner writes

Nobody else can deposit on your nodes.

Double Ratchet

New keys for every message; old ones stay protected.

Sealed server keys

Encrypted on disk. Locked after a restart until your app releases it.

Steady rhythm

The app polls at a fixed rhythm and deposits cover traffic. Real messages do not stand out.

COMPLIANCE BY ARCHITECTURE

There is no provider that can be forced to hand over data.

NexonAI runs no servers and processes no data on the customer's behalf.

Data protection by design (Art. 25 GDPR).

The data stays entirely within your own infrastructure.

LICENCE

Tiered by size, checked offline

5	25	100	250
Nodes per server	Nodes per server	Nodes per server	Nodes per server

One licence code per server. It is checked on the server only; nothing is sent to us. When the licence expires, the server accepts no new messages; existing ones can still be collected.

Apps: licence per user, term from one month to one year, also checked offline.

WHO IT IS FOR

Wherever confidentiality is a duty

Law firms

Client communication under professional secrecy.

Healthcare

Patient data without third-party providers.

Tax

Sensitive financial documents.

Management

Strategy, mergers, acquisitions.

Public authorities

Internal communication without a foreign cloud.

CURRENT STATUS

Built and tested. Next step: real devices.

Done

Server: 123 automated tests, without the live Tor network (one skipped). Tablet node: 15 tests. App: 181 tests, the same in every edition.

Next

Test on real devices. Measurement on a real VPS. Independent security audit.

No architecture protects against a phone with spyware or a partner who takes screenshots.

NEXT STEPS

A pilot.
Your system.

1. Analyse needs and communication paths
2. Install your own servers and apps, activate the licence
3. Pilot with one team, then roll out
